Abstract

Background & Objective: The Hidden Curriculum (HC) represents the cultural process of medical training, where students acquire attitudes and values. Understanding the HC enables educators to develop more impactful learning experiences. Therefore, this study aims to assess the perceptions of Al-Neelain University dental students regarding the frequency and impact of positive and negative aspects of the HC.

Materials & Methods: A cross-sectional study was conducted among a randomly selected sample of fifth-year dental students at Al-Neelain University (Sudan). Data were collected using the self-administered Hidden Informal Curriculum Assessment Tool (HICAT). The data were analyzed using the Mann-Whitney U test, Kruskal-Wallis test, and McNemar test.

Results: The response rate was 100% (81 out of 81), with 70.3% of respondents identifying as female. Approximately 53% of the respondents were single, and 86.4% were citizens. The most commonly reported positive scenario was a satisfactory patient-doctor consultation, noted by 60% of participants. In contrast, the least frequently observed positive scenario was the presence of high professional standards in their learning environments, reported by only 25%. On the negative side, the most frequently cited issue was discriminatory attitudes in learning environments, affecting 52% of respondents. Conversely, ethnic discrimination and gender discrimination were the least frequently reported negative scenarios, at 7% and 9%, respectively. Data revealed a statistically significant association between perceptions of certain HC scenarios and gender ($p = 0.047$), Citizenship ($p = 0.045$), and social status ($p = 0.003$). The top two influential scenarios identified were having a positive role model doctor and developing strong patient-doctor skills.

Conclusion: Respondents frequently reported positive patient-doctor consultations, while discriminatory attitudes in learning environments were the most common negative scenario. Understanding students' perceptions of healthcare is essential, as it can help reinforce positive aspects and improve negative ones in the future.

Keywords: hidden curriculum, dental students, training, professionalism, role model, Sudan

Introduction

The curriculum is the practical application of all educational concepts [1], including null, social, and received curricula [2]. The Hidden Curriculum (HC) refers to the unwritten, implicit, unofficial, and unintended lessons, values, and perspectives students acquire during their undergraduate studies, alongside the formal aspects of education [3, 4]. According to its

focus, HC can be classified into two types: A cold curriculum, which emphasizes redundancy and offers low reward value, and a hot curriculum, which prioritizes high-reward elements such as behaviors, norms, values, gender roles, and political preferences. The hot curriculum is primarily learned through direct reinforcement and identification [5-7]. Bloom's

redundancy theory posits that the HC, when consistently presented over time, has a greater impact on students' memory than the manifest curriculum [8]. Furthermore, the effectiveness of learning through redundant information largely depends on how compatible that information is with the learner's cognitive structures and its high reward value [5]. Furthermore, previous research has identified a positive and significant correlation between elements of the HC and the level of academic achievement attained by students [9]. In the medical field, including medicine and dentistry, the HC plays a crucial role in the development of physicians. As opposed to the formal curriculum that occurs in the classroom through lectures, the HC exemplifies the "cultural process" of medical training through the socialization of physicians, as they internalize the behaviors, attitudes, and values that are modeled to them in the "moral community" of medical school. This process starts early in the first year of training and continues throughout residency [10]. The elements of HC include providing role models to emulate, establishing medical ethical standards, implementing rules and regulations, introducing medical terminology and jargon, fostering professionalism, and understanding the power hierarchy within medicine. The effectiveness of these elements can be positively or negatively influenced by the manner in which the HC is communicated [11-13]. Medical schools prepare students for careers in medicine by integrating cognitive knowledge, role modeling, organizational culture, stereotyping, and professional attire, all of which contribute to the development of professionalism and professional identity [14]. The HC is a subject of ongoing debate, with some advocating for its positive aspects while others point out its potential negative effects [15]. Understanding the HC significantly enhances the teaching staff's attitudes toward students and trainees, as they become more aware of its influence and importance. Without this awareness, they may send harmful social beliefs and ideas, hindering social change [16]. This study aims to assess the perceptions of fifth-year dental students at Al-Neelain University regarding the practice and impact of the HC. The findings from this study will be instrumental in identifying gaps that need to be addressed in the HC from the students' perspectives.

Materials & Methods

Design and setting(s)

A descriptive cross-sectional study was conducted at the Faculty of Dentistry at Al-Neelain University, which was

established in 2005. It has a distinct curriculum with clear goals and vision towards society; it includes a total of 11 semesters. The faculty has 12 departments in various dental specialties. The faculty offers students advanced training in dentistry through clinics and industrial replacement laboratories. They participate in activities like therapeutic days and educational visits to achieve the college's vision. Students receive early clinical training along with comprehensive patient care. The study was conducted from September 2021 to June 2022.

Participants and sampling

The study focused on undergraduate fifth-year students at the Faculty of Dentistry at Al-Neelain University. It included both female and male fifth-year students who were registered in the bachelor's degree program in dentistry, as well as foreign students. Students who were not registered for courses during the study period were excluded. According to the records from the Al-Neelain University Faculty of Dentistry, there are 102 students enrolled in the fifth year. The minimum sample size required for the study was calculated to be 81, using the Open-Source Epidemiologic Statistics for Public Health Version 3.01 online calculator, with a confidence level of 95% [17]. For sampling, systematic random sampling was employed, utilizing the list of fifth-year students as the sampling frame. The sampling interval was determined by dividing the total population size ($N = 102$) by the desired sample size [18]. The first participant was selected by simple random sampling.

Tools/Instruments

The data were collected online using a self-administered questionnaire as a data collection tool. The questionnaire consisted of two sections. The first section examined the sociodemographic characteristics of the participating students. The second section contained the Hidden Curriculum Assessment Tool (HICAT) [18]. The questionnaire consisted of four sections and comprised 27 items. The first section consisted of four questions to explore the socio-demographic characteristics of the participants.

The second section outlines ten positive HC scenarios that students may have experienced during their studies. The third section features ten negative HC scenarios. The fourth section, titled "Impact Rating," requests students to identify the three scenarios that had the most significant impact on them during their clinical rotations, selecting from the previously mentioned 20 scenarios. This section emphasizes the depth of the impact rather

than the frequency with which the scenarios were encountered. In the first and second sections of the questionnaire (comprising ten positive and ten negative HC scenarios), participants' responses were rated using a modified 4-point Likert scale: 1. Usually/Always, 2. Half the time, 3. Never/Occasionally, 4. Not applicable. Permission to use HICAT was obtained via email correspondence from Prof. Paul McGurgan, the originator of the questionnaire at the University of Western Australia. HICAT is used to quantify both the frequency of positive and negative aspects of the HC and the impact of these experiences on dental students. It was developed in two main steps. Initially, the authors developed a range of educational scenarios related to the HC based on a literature review, intending to capture both positive and negative aspects. Subsequently, a focus group of medical students reviewed and refined these scenarios, selecting the most relevant ones based on their individual experiences. The most common scenarios (ten negative and ten positive) served as the foundation for the instrument. After that, the instrument was piloted on a second rotation of medical students to ensure its user-friendliness and internal validity [18]. To ensure validity within our context, the questionnaire was reviewed by a panel of four experts who critically evaluated its content and relevance. The instrument demonstrated acceptable reliability, with a Cronbach's Alpha of 0.682.

Data collection methods

Before administering the HICAT questionnaire, fifth-year dental students were provided with information about the study. This included a definition of the HC, assurances of confidentiality, and a statement indicating that participation was voluntary and would not affect their academic outcomes. The online HICAT questionnaire was created using Google Forms and was subsequently hosted online via a unique URL. Pre-selected study participants were invited individually to participate through their contact information. Participants' responses were automatically collected and stored in a Google Drive.

Data analysis

The Statistical Package for Social Sciences (SPSS) version 17 was utilized for coding, entering, and analyzing participants' responses. Descriptive analysis was conducted to summarize the data, with frequency and percentages calculated for categorical variables, and mean and standard deviation employed for continuous variables. Non-parametric statistics were used to identify

significant differences or associations between independent and dependent variables. The non-parametric tests applied included the Mann-Whitney U test, Kruskal-Wallis test, and McNemar test. A p-value of 0.05 or less was considered statistically significant.

Results

The response rate was 100% (81 out of 81 participants). As shown in **Table 1**, the majority of respondents were females (70.3%). More than half (53%) of the respondents were single, and a significant proportion (86.4%) were citizens. Additionally, all respondents identified as Muslims (100%).

Table 1. Sociodemographic characteristics of participants (n = 81)

Characteristics	Frequency	Percent
Gender	Male	24
	Female	57
Citizenship	Citizen	70
	Foreign	11
	Single	65
Social status	Married	9
	Married with children	7
Religion	Muslim	81
	Christian/Others	0

As shown in **Table 2**, the most highly valued positive scenarios reported by respondents included observing positive patient-doctor consultations (60%), followed by witnessing health professionals educating patients about their conditions (56%), encountering health professionals regarded as positive role models (49%), and observing staff acknowledging their limitations (49%). The least frequent items observed were observing high professional standards in their learning environments (25%) and observing patients being treated as unique individuals (28%). Regarding the negative HC scenarios (**Table 3**), the most frequent scenario was discriminatory attitudes in learning environments (52%). The least frequent negative scenarios were discrimination due to ethnic background (7%) or gender (9%), followed by feeling humiliated by a supervisor (21%). Participants' responses were analyzed in relation to their demographic data to identify potential associations between demographic factors and perceptions of HC scenarios. Among positive and negative scenarios, only those demonstrating a significant association between demographic factors and student responses were discussed. Females were more often asked to undertake unsupervised tasks whilst

feeling unconfident ($p = 0.047$) and were more troubled by the experiences encountered than their male counterparts ($p = 0.015$). On the other hand, males reported feeling disadvantaged due to their ethnic background more often than females ($p = 0.047$) and felt more supported during their placements ($p = 0.045$). Additionally, data analysis revealed a statistically

significant association between citizenship and three HC scenarios. Citizens were more frequently asked to undertake unsupervised tasks while feeling unconfident ($p = 0.045$) and were observed to develop doctor-patient skills more often than foreign students ($p = 0.018$). In contrast, foreign students felt disadvantaged because of their ethnic background ($p = 0.001$).

Table 2. Responses of the participants to the positive hidden curriculum scenarios

Scenario	Usually/Always n (%)	Half the time n (%)	Never/Occasionally n (%)	Not applicable n (%)
I felt supported during my placements	33 (40.74)	27 (33.33)	20 (24.69)	1 (1.23)
I have encountered health professionals I consider were positive role models	40 (49.38)	28 (34.57)	12 (14.81)	1 (1.23)
I have observed health professionals dealing with complex cases in a positive manner	39 (48.15)	25 (30.86)	15 (18.52)	2 (2.47)
I have observed health professionals educating patients about their condition	45 (55.56)	25 (30.86)	10 (12.35)	1 (1.23)
I have observed high professional standards in my learning environments	20 (24.69)	26 (32.10)	30 (37.04)	5 (6.17)
I have observed patients being treated as unique individuals	23 (28.40)	33 (40.74)	22 (27.16)	3 (3.70)
I have observed positive patient-doctor consultations	49 (60.49)	22 (27.16)	10 (12.35)	0 (0.00)
I have witnessed health professionals going out of their way to assist colleagues	33 (40.74)	27 (33.33)	20 (24.69)	1 (1.23)
I have witnessed staff acknowledging their limitations	40 (49.38)	28 (34.57)	12 (14.81)	1 (1.23)
I was inspired to develop my doctor-patient skills	39 (48.15)	25 (30.86)	15 (18.52)	2 (2.47)

Abbreviations: n, number of participants; %, percentage.

Table 3. Responses of the participants to the negative hidden curriculum scenarios

Scenario	Usually/Always n (%)	Half the time n (%)	Never/Occasionally n (%)	Not applicable n (%)
I felt disadvantaged because of my ethnic background	6 (7.41)	6 (7.41)	55 (67.90)	14 (17.28)
I felt disadvantaged because of my gender	7 (8.64)	13 (16.05)	47 (58.02)	14 (17.28)
I have encountered health professionals I consider were negative role models	23 (28.40)	28 (34.57)	23 (28.40)	7 (8.64)
I have felt humiliated by a supervisor	17 (20.99)	22 (27.16)	39 (48.15)	3 (3.70)
I have observed poor inter-professional teamwork	35 (43.21)	28 (34.57)	16 (19.75)	2 (2.47)
I have witnessed discriminatory attitudes in learning environments	42 (51.85)	17 (20.99)	20 (24.69)	2 (2.47)
I heard judgmental remarks about a patient in the clinical workplace	17 (20.99)	31 (38.27)	31 (38.27)	2 (2.47)
I needed to compete with other dental students	25 (30.86)	20 (24.69)	31 (38.27)	5 (6.17)
I was asked to undertake a task I was not confident to perform unsupervised	21 (25.93)	28 (34.57)	29 (35.80)	3 (3.70)
I was troubled with the experiences I encountered during my placements	22 (27.16)	21 (25.93)	33 (40.74)	5 (6.17)

Abbreviations: n, number of participants; %, percentage.

The social status of the respondents was significantly associated only with doctor-patient consultations ($p = 0.035$) (Table 4). Respondents reported two positive scenarios and one negative scenario as their three most influential HC scenarios. The most impactful positive scenarios identified were “I have encountered health professionals I consider to be positive role models” and “I was inspired to develop my doctor-patient skills.” In

contrast, the most frequently reported negative scenario was “I needed to compete with other dental students” (Table 5).

Furthermore, data analysis showed a significant difference between the most impactful negative scenario and each of the two most frequently cited positive scenarios, with p-values of 0.046 and 0.040, respectively (Table 6).

Table 4. Association between sociodemographic characteristics of the participants and the hidden curriculum scenarios

Scenario	Variable	Response (Number (%))				Sig.
I was asked to undertake a task I was not confident to perform unsupervised	Gender	Usually/Always n (%)	Half of the time n (%)	Never/Occasionally n (%)	Not applicable n (%)	Z = -1.987 P = 0.047*
	Male	3 (12.50)	9 (37.50)	12 (50.00)	0 (0.00)	
I felt disadvantaged because of my ethnic background	Female	18 (31.58)	19 (33.33)	17 (29.82)	3 (5.26)	Z = 1.990 P = 0.047*
	Male	3 (12.50)	4 (16.67)	15 (62.50)	2 (8.33)	
I was troubled with the experiences I encountered during my placements	Female	3 (5.26)	2 (3.51)	40 (70.18)	12 (21.05)	Z = -2.427 P = 0.015*

	Single	43 (66.15)	18 (27.69)	4 (6.15)	0 (0.00)	

Notes: *Mann-Whitney U test was used to compare association between gender, citizenship and the hidden curriculum scenarios, **Kruskal-Wallis test was used to compare the association between social status and the hidden curriculum scenarios.

Abbreviations: N, frequency ;Sig, statistical significance; p, probability -value; Z, z-score (standardized Mann-Whitney U test test statistic); H, Kruskal-Wallis test statistic

Table 5. The participants' rankings of hidden curriculum scenarios

The most impactful scenarios	Times selected	Percent (%)	Percent of respondents (%)
I have encountered health professionals I consider were positive role models	55	22.63	67.90
I have observed patients being treated as unique individuals.	9	3.70	11.11
I needed to compete with other dental students	26	10.70	32.10
I was asked to undertake a task I was not confident to perform unsupervised	9	3.70	11.11
I have observed poor inter-professional team work	9	3.70	11.11
I was inspired to develop my doctor-patient skills	40	16.46	49.38
I heard judgmental remarks about a patient in the clinical workplace	6	2.47	7.41
I have witnessed staff acknowledging their limitations	6	2.47	7.41
I have observed positive patient-doctor consultations	4	1.65	4.94
I have witnessed discriminatory attitudes in learning environments	8	3.29	9.88
I have felt humiliated by a supervisor	9	3.70	11.11
I have encountered health professionals I consider were negative role models	9	3.70	11.11
I felt disadvantaged because of my gender	8	3.29	9.88%
I felt disadvantaged because of my ethnic background	4	1.65	4.94
I was troubled with the experiences I encountered during my placements	8	3.29%	9.88
I have observed health professionals educating patients about their condition	3	1.23%	3.70
I have observed high professional standards in my learning environments	7	2.88%	8.64
I have witnessed health professionals going out of their way to assist colleagues	7	2.88%	8.64
I have observed health professionals dealing with complex cases in a positive manner	7	2.88%	8.64
I felt supported during my placements	9	3.70%	11.11
Total	243	100	300

Note: Times selected, the frequency with which a specific scenario was chosen by the participants; Percent (%), the proportion of times a given experience was selected based on n = 243; percent of respondents(%), the proportion of respondents who selected each experience based on n = 81, acknowledging that each respondent could select more than one experience.

Table 6. Comparison between the three most impactful scenarios

Scenarios	Times selected	Sig.
I have encountered health professionals I consider were positive role models	55	$\chi^2=4.000$
I was inspired to develop my doctor-patient skills	40	p = 0.046*
I needed to compete with other dental students	26	$\chi^2=4.225$
I was inspired to develop my doctor-patient skills	40	p = 0.040*

Note: McNemar test used to compare between the most impactful scenarios, the three most impactful scenarios are having a positive role model doctor, the aspiration to develop strong patient-doctor skills and the need to compete with other medical students; Times selected, the number of times each experience was reported across all responses.

Abbreviations: Sig, statistical significance; p, probability -value; χ^2 , Chi -square statistic.

Discussion

This study aimed to identify positive aspects of the HC that can be reinforced, while also identifying negative aspects that should be avoided or reshaped. The ultimate goal is to improve the cultures of both the health professions and education. The HICAT was utilized to measure both the frequency of dental students' experiences with HC scenarios and the impact of these experiences. This tool is useful for evaluating medical students in clinical and educational settings to determine their strengths and weaknesses [18]. Among the ten positive scenarios, the majority of students in this study observed a positive attitude during patient-doctor consultations. Patients expressed a desire to be informed about their condition and to receive support from their doctors. These findings align with results from a study conducted at the University of Western Australia, where 93% of students agreed on the same scenarios [18]. Additionally, our findings are partially in line with the findings of a study conducted in Pakistan, where medical students highly valued the demonstration of high professional standards, the exhibition of positive role modeling, and positive doctor-patient relationships [19]. Moreover, a qualitative study among dental students in Iran demonstrated the importance of considering a professor's professional behavior and their role as a role model [20]. The least frequently observed positive scenarios were "observing patients being treated as unique individuals" and "observing high professional standards in the learning environments." Our findings contrast with a study conducted in Pakistan, where the least valued items were observing staff admitting their limitations and witnessing health professionals effectively managing complex cases in a positive manner [19]. These differences could be attributed to differences in participants' social culture. Professionalism is a culture-dependent ability and training for all professional responsibilities is a difficult task that comes with many obstacles as stated in many studies [21, 22]. The gap between knowledge and practice, a lack of emphasis on continuous professional education, the normalization of certain behaviors, and the neglect of the importance of being observed as a role model were identified as justifications for these findings, which can also be relevant to the Sudanese context [23]. Regarding negative scenarios, the most common experience reported was witnessing discriminatory attitudes in learning environments (52%). This finding aligns with a survey conducted among internal medicine trainees in the United States, where nearly two-thirds of respondents

reported observing unequal treatment of patients from various backgrounds [24]. Discriminatory attitudes in the learning environment can negatively affect students' educational outcomes. Efforts should be directed to address and implement strategies to eliminate such attitudes and maintain health equity. Furthermore, there is a need to train dental students and educators on how to effectively respond to any form of prejudiced attitudes. Conversely, the least frequently observed negative scenarios included disadvantages faced by students due to their gender (9%) or ethnic background (7%). This latter finding is somewhat unexpected, given the ethnic diversity in the country and the reported discrimination claims and conflicts between tribes. Additionally, the issue of gender equity within the educational environment is noteworthy. Education for women in Sudan began as early as 1903 [25], and since then, women have made significant strides in education and have become major contributors to society. Data analysis showed a statistically significant association between gender and confidence to perform unsupervised tasks. Females were more often asked to undertake unsupervised tasks whilst feeling unconfident. Similarly, females were observed to be troubled half of the time by the new experiences they encounter ($p = 0.015$) than their male counterparts. The majority of them never had that feeling and were able to deal with the new experiences in their workplace easily despite their feeling unsupported. The transition from medical student to practicing physician in real-world clinical settings is a significant challenge. They often experience significant stress during their clinical practice. This period of clinical training usually is case-based hands-on learning with real patients. This can lead to significant stress for graduating students, as they often feel unprepared for the multitasking responsibilities and heavy workload they face [26]. Other studies suggest that the cause of unpreparedness is due to lack of hands-on practice [27, 28]. Fortunately, new clinically oriented assessment tools, such as the Objective Structured Clinical Examination (OSCE), Direct Observation of Procedural Skills (DOPS), and Mini Clinical Evaluation Exercise (Mini-CEX) have been adopted by most of medical schools [29-31]. On the other hand, males reported feeling disadvantaged due to their ethnic background and felt more supported during their placements compared to females. In contrast, a paper published in England indicates that racism remains a significant issue in British schools, with progress in that area being the exception rather than the norm [32]. Furthermore, a longitudinal

study conducted in the United States from 2010 to 2014 revealed that racism in American medical schools manifested at multiple levels, highlighting the need for strategies to eliminate structural racism within these institutions [33]. The study showed a statistically significant association between citizenship and feeling disadvantaged because of ethnic background. Foreign students were feeling disadvantaged because of their ethnic background.

The difficulty in feeling integrated can be attributed to the mixed Arab-African Sudanese ethnic background, which may prevent some individuals from fully integrating into Sudanese society. Additionally, foreign students may find it challenging to develop communication with patients due to factors in the host environment, such as cultural differences, social behaviors, and language barriers. This issue is not unique to Sudan; discriminatory treatment has also been reported among international students enrolled in American colleges and universities [34]. Given that the presence of dental students from diverse ethnic backgrounds can significantly enrich classroom cultural diversity and the overall academic environment, it is essential to foster integration among students through social support services and cultural events [35]. In recent years, global interconnectedness through trade, technology, and education has increased significantly. Moreover, the Arab Spring uprisings in some countries have led to widespread migration within the region, contributing to a substantial growth in the international student population at Sudanese universities. While international students present challenges, they also offer valuable opportunities.

Regarding the most impactful HC scenarios, having a positive role model doctor and the aspiration to develop strong patient-doctor skills were identified as the top two influential scenarios. Our finding aligns with previous research indicating the crucial role of medical teachers and staff in fostering the professional identity of medical students and preparing them for future medical careers. Students' perception of their clinical tutor's behavior, interactions, work ethics, and skills can significantly influence their choice of clinical field for residency training [36-38]. Role models are often used by medical teaching staff to impart professional values, attitudes, and behaviors to their students as part of the informal medical training curriculum [36, 39]. In our culture, a role model doctor is perceived as one who establishes a strong connection with their patients and their families, demonstrating thoughtfulness and fostering extended

social relationships. This area needs further studies to elaborate differences between cultures. The second impactful scenario was inspiration to develop a patient-doctor relationship. The doctor-patient relationship is a consensual agreement where the patient seeks the physician's help, the physician accepts them as a patient, respects their autonomy, maintains confidentiality, explains treatment options, obtains informed consent, and provides the best care [40]. Doctor-patient skills are fundamental elements for high-quality healthcare. A systematic review including qualitative and quantitative studies concluded that various aspects of the doctor-patient relationship including communication, significantly impact both objective and subjective health outcomes [41]. In a recent study among dental students at Babol University of Medical Sciences (Iran), Students considered interaction and communication between the professors, students, and staff as crucial themes within the HC (20). Acknowledging the complexity of the doctor-patient relationship and its variations across cultures and backgrounds, educators have developed a range of curricula to teach students how to effectively interact with diverse patient populations [42]. The final most impactful scenario noted was the need to compete with other medical students, which aligns with findings from a study conducted among medical students in Pakistan [19]. While competition can be a powerful motivator, encouraging individuals to reach their highest potential, it can also have unfavorable effects if it goes too far. Kusnoor et al. highlights the negative impact of student competition on medical education and patient care [43]. Students facing time pressure and high competition may neglect some physical exams and pertinent historical information, potentially leading to costly mistakes.

Moreover, competition can negatively affect medical students' empathy toward patients due to burnout and stress, as they tend to prioritize task completion over patient care [44]. To foster intrinsic motivation among students, learning programs should emphasize collaborative and multifaceted teaching and learning strategies rather than competitive and simplistic approaches [45]. One potential limitation of this study is that it was conducted at a single governmental university in Sudan, which may restrict the generalizability of the findings, as they may not be representative of dental education as a whole. Additionally, this was a cross-sectional study administered to students all at once; however, as students' encounter various experiences, their perceptions may evolve.

Conclusion

The study revealed that the most frequently observed positive scenario among students was a positive patient-doctor consultation (60%), while the least observed scenario was related to high professional standards in their learning environments (25%). In terms of negative scenarios, the most commonly reported issue was discriminatory attitudes in learning environments (52%), whereas ethnic and gender discrimination were the least frequent at 7% and 9%, respectively. This study provides a foundational understanding of the perceptions of Al-Neelain dental students regarding the HC. Further research is needed to explore the characteristics of a positive role model in accordance with cultural values in order to enhance the HC. Additionally, essential concepts of the hidden curriculum should be incorporated into the written curriculum, along with effective faculty training.

Ethical considerations

Approval for the research proposal and ethical clearance were obtained from the Sudan Medical Specialization Board Ethical Committee (SMSB-REC-13.9.2021). Participant agreement was secured through informed consent, which involved explaining the research title and purpose in clear and simple terms.

Only data relevant to the study's purpose was collected, and confidentiality was maintained throughout the research process.

Artificial intelligence utilization for article writing

Artificial intelligence was not used to write the article

Acknowledgment

We gratefully acknowledge all the faculty and members of the Educational Development Center (EDC) at Sudan Medical Speciation Board (SMSB) for being a great help throughout our study period. The authors would also like to thank The faculty of Dentistry (Al-Nileen University) and students who participated in the study.

Conflict of interest statement

The authors report no conflicts of interest in this work.

Author contributions

Conceptualization and Planning: SAA, BH, AHA, Data Collection: SAA, BH, Data Analysis: SAA, BH, Project Administration: SAA, BH, Resources: SAA, BH,

Writing - Original Draft: SAA, BH, AHA, Writing - Review & Editing: SAA, BH, AHA

Funding

The work was conducted as a part of the health professional education program at the Sudan Medical Speciation Board (SMSB), and no grants or financial support were received.

Data availability statement

All data collected for this study will be available upon request.
